

Search Engine Optimisation

How to make the Orvinex landing page rank — concepts explained, current state audited, and the work ranked by what actually moves the needle.

Prepared for Orvinex Software Solutions

orvinex.store · 1 August 2026

What this covers

Four things, in order: how a search engine actually processes your page; the vocabulary you need to follow any SEO discussion; an honest audit of where the Orvinex landing page stands today; and a ranked plan of what to do next.

The one-sentence version

Your technical foundation is already strong — the page ships complete HTML and now carries structured data. The remaining gains are not technical tweaks; they come from content depth, more indexable pages, and earning links.

1. How a search engine sees your page

Ranking is the last step of a four-stage pipeline. A failure at any earlier stage means the later ones never happen — which is why 'my page will not rank' is usually a crawling or indexing problem, not a ranking one.

- | | |
|------------------|---|
| 1. CRAWL | A bot requests your URL and downloads the raw HTML. Governed by robots.txt. |
| 2. RENDER | The bot runs your JavaScript in a headless browser to see the final DOM. Queued separately and not guaranteed to be fast. |
| 3. INDEX | The content is parsed, understood, and stored. Google decides here whether you are worth keeping at all. |
| 4. RANK | For a given query, the index is sorted by relevance, quality, and authority. |

Why 'static HTML' matters

If your content only exists after JavaScript runs, you depend entirely on stage 2. Google does render JS, but it is queued and can lag by days. Most other crawlers — LinkedIn and WhatsApp previews, and the AI engines — skip rendering entirely and only ever see stage 1. Shipping finished HTML removes that dependency.

2. The three pillars

Technical SEO — can the machine access and understand it?

Crawlability, indexability, site speed, mobile rendering, structured data. Largely a solved, one-time engineering job. This is where Orvinex is strongest.

On-page SEO — is the content the best answer to the query?

Titles, headings, body copy, internal links, images. Depends on how many distinct topics you cover and how well. This is where the current single-page site is weakest.

Off-page SEO — does anyone else vouch for you?

Mostly backlinks: other reputable sites linking to yours, each treated as a vote of confidence. The slowest to build, the hardest to fake, and the biggest differentiator in competitive markets.

3. Terms you need

Rendering strategies

CSR Client-Side Rendering. The server sends an empty shell plus a JS bundle; the browser builds the page. Worst case for crawlers.

SSR Server-Side Rendering. HTML is generated on the server on every request. Complete HTML, but slower first byte and a running server per hit.

SSG Static Site Generation. HTML is generated once at build time and served as a file. Complete HTML and the fastest possible delivery. This is what Orvinex uses.

ISR Incremental Static Regeneration. SSG that rebuilds itself on a timer. The right answer if your copy later moves into a CMS.

SSR vs SSG for SEO

A crawler cannot tell them apart — both deliver finished HTML in the first response, and there is no signal saying which produced it. SSG simply arrives faster, which helps Core Web Vitals. Switching a marketing page from SSG to SSR gains nothing for SEO and costs speed.

Crawling and indexing

robots.txt A file at your domain root telling bots which paths they may fetch. Controls crawling only.

noindex A meta tag telling search engines not to list a page. This is what actually removes a page from results — and the bot must be allowed to crawl the page to see it. Blocking a URL in robots.txt while also trying to noindex it means neither works.

sitemap.xml A machine-readable list of the URLs you want indexed. Aids discovery. Near-useless on a one-page site; essential once you have dozens.

Canonical URL A tag declaring the single official address for a page. Prevents duplicate-content dilution when the same content is reachable at several URLs — with and without a trailing slash, with tracking parameters, http and https.

Two-wave indexing Google indexes raw HTML immediately, then queues JavaScript rendering for later. Content that only appears after JS may wait days for the second wave.

Structured data

Schema.org A shared vocabulary for describing things — organisations, people, products, articles — in terms machines understand.

JSON-LD The preferred format for that vocabulary: a JSON block in a script tag, invisible to users. Prose says you build software; JSON-LD states that you are a ProfessionalService with a founder, a service catalogue, and a service area.

Rich result An enhanced search listing — star ratings, FAQ dropdowns, logos. Earned through structured data; lifts click-through rate.

Knowledge panel The entity card on the right of a results page. Requires Google to recognise you as a distinct entity, which structured data plus consistent off-site references makes possible.

Performance — Core Web Vitals

Three measured signals, used as a real if modest ranking factor. They are measured on real visitors, not in a lab.

LCP Largest Contentful Paint. Time until the biggest element — usually the hero heading or image — is visible. Target under 2.5 seconds.

INP Interaction to Next Paint. How quickly the page responds to a tap or click. Target under 200 milliseconds.

CLS Cumulative Layout Shift. How much content jumps around while loading. Target under 0.1. Caused mainly by images without dimensions and late-loading fonts.

The trap in animated landing pages

Scroll-reveal animations that start elements at opacity:0 bake that invisible state into the served HTML. The text is present and crawlable, but nothing is visible until JavaScript loads and hydrates — so your LCP is pushed back by the full cost of hydration, and the page is blank if JS fails. Animate with CSS so the first paint is already meaningful.

Measurement and results

SERP Search Engine Results Page — the page of results itself.

CTR Click-Through Rate. The share of people who see your listing and click it. Driven by your title and description, and an indirect quality signal.

Impressions How often your page appeared in results, whether clicked or not. The clearest measure of visibility.

Search Console Google's free tool showing your impressions, clicks, average position, and indexing errors. Non-optional: without it you are guessing.

Authority and content

Backlink A link to you from another site. The strongest off-page signal. Quality vastly outweighs quantity.

Anchor text The visible words of a link. Tells search engines what the destination is about.

E-E-A-T Experience, Expertise, Authoritativeness, Trustworthiness. Google's framework for assessing quality. Named authors, real credentials, genuine case studies, and clear contact details all feed it.

Keyword intent Why someone searched. Informational ('what is an ERP'), commercial ('best software agency'), or transactional ('hire developers'). One page can serve one intent well — which is why one page cannot rank for everything.

4. Where the Orvinex page stands

ITEM	STATUS	NOTE
Static HTML to crawlers	DONE	Prerendered via SSG; full copy in the first response.
Title and meta description	DONE	Present and within display limits.
JSON-LD structured data	DONE	Organization + ProfessionalService, founder, services, WebSite, WebPage.
robots.txt	DONE	Serving; crawling fully open.
Favicon and app icons	DONE	icon.png and apple-icon.png detected by the framework.
Semantic headings	DONE	One H1, five H2s, sensible hierarchy.
Open Graph / Twitter tags	PARTIAL	Tags exist, but the card declares a large image and none is defined.
Canonical URL	MISSING	No canonical set; duplicate-URL variants can dilute signals.
sitemap.xml	MISSING	Low value at one page, but needed before expanding.
Social profiles (sameAs)	MISSING	Footer links are placeholders; entity cannot be cross-verified.
LCP / hero visibility	GAP	H1 ships at opacity:0 and waits for hydration to appear.
Image weight	GAP	founder.png is 3.3 MB; should be compressed at source.

Indexable page count	GAP	One URL chasing seven distinct commercial keywords.
Content / articles	MISSING	The Articles link points at nothing. No informational content.
Backlink profile	MISSING	No off-page work started.
Google Search Console	MISSING	Not verified; no visibility into actual performance.

5. What to do, in order

#	ACTION	IMPACT	EFFORT
1	Verify the domain in Google Search Console and submit the sitemap.	High	30 min
2	Add a canonical URL so every variant resolves to one address.	Medium	5 min
3	Add an Open Graph share image (1200x630) so links render properly.	Medium	30 min
4	Add sitemap.ts and wire the Sitemap line into robots.txt.	Low	10 min
5	Fix the opacity:0 hero so first paint is visible without JS.	High	1-2 hrs
6	Compress founder.png and any other oversized assets.	Medium	15 min
7	Create real social profiles and add them as sameAs in the schema.	Medium	1 hr
8	Split services into dedicated pages, one intent per URL.	High	1-2 wks
9	Ship the Articles section with genuine technical writing.	High	Ongoing
10	Publish detailed case studies with named clients and outcomes.	High	Ongoing
11	Earn backlinks: directories, guest posts, open-source, communities.	High	Ongoing

Where the ceiling actually is

Items 1-7 are finishing touches on an already-solid technical base; together they are perhaps a day of work and they close every remaining technical gap. But they will not, on their own, move you up the rankings much. Items 8-11 are where the real traffic lives, and they are measured in months, not hours. Technical SEO gets you eligible to compete. Content and links are how you win.

6. Landing-page specifics

One page, one intent

A single URL realistically ranks for one cluster of closely related queries. Targeting 'software agency', 'AI development', 'mobile apps' and 'SEO services' from the same page means each dilutes the others. Give every service its own URL with its own H1, its own copy, and its own metadata — then link them from the homepage.

Write the title tag for a human

It is the single highest-leverage line on the site: it is your headline in the results page and the main driver of click-through. Keep it under about 60 characters, lead with what you do, and put the brand name last.

Depth beats keyword density

Stuffing a phrase repeatedly has not worked for over a decade and now reads as spam. Comprehensiveness wins: cover the topic properly, answer the follow-up questions, and cite specifics.

Make credibility machine-readable

Named founder with real credentials, verifiable testimonials, visible contact details, and a physical presence all feed E-E-A-T. Fabricated testimonials are both a legal exposure and a trust risk — replace placeholders with real quotes before driving traffic.

7. Verification checklist

Run these against the production domain after every deploy. Each answers a specific question with a specific tool.

Is the content really in the HTML?

```
curl -s https://orvinex.store | grep -o "Rohan Kumar Singh"
```

If that prints, a crawler sees your content with no JavaScript involved. This is the single most useful SEO check there is.

- ☐ Rich Results Test (search.google.com/test/rich-results) — confirms the JSON-LD parses and shows which rich results you qualify for.
- ☐ Schema validator (validator.schema.org) — stricter vocabulary checking than Google's tool.
- ☐ PageSpeed Insights (pagespeed.web.dev) — lab and field Core Web Vitals. Read the field data first; it reflects real users.
- ☐ Search Console URL Inspection — shows exactly how Google rendered the page and whether it is indexed.
- ☐ Mobile check — the majority of traffic and the version Google indexes.
- ☐ Social preview — paste the URL into LinkedIn or Slack and confirm the card renders with an image.
- ☐ robots.txt and sitemap.xml both resolve and do not 404.

Test against a production build, never the dev server

Development mode renders every request on the fly and skips static optimisation entirely. Inspecting HTML while running the dev server will show different behaviour and lead to wrong conclusions. Always check a real build, or the live domain.

Closing note

SEO has no finish line, but it does have a clear order of operations. The technical layer — which is where most of the work so far has gone — is a prerequisite, not a strategy. It makes you eligible. What earns rankings after that is publishing genuinely useful content on well-structured pages and giving other people a reason to link to it. Everything in section 5 below item 7 is the real programme; everything above it is housekeeping that should be finished this week and then forgotten.
